

# # HashMap

→ It is a type of Data Structure  
→ which stores  $\langle \text{key}, \text{value} \rangle$  pair data.

→ In C++, we have two types of HashMap

Ordered map

↓  
Take  $O(\log n)$  TC  
for Insertion,  
deletion,  
searching

Unordered Map.

↓  
Take  $O(1)$  TC  
for Insertion,  
Deletion Search  
ing

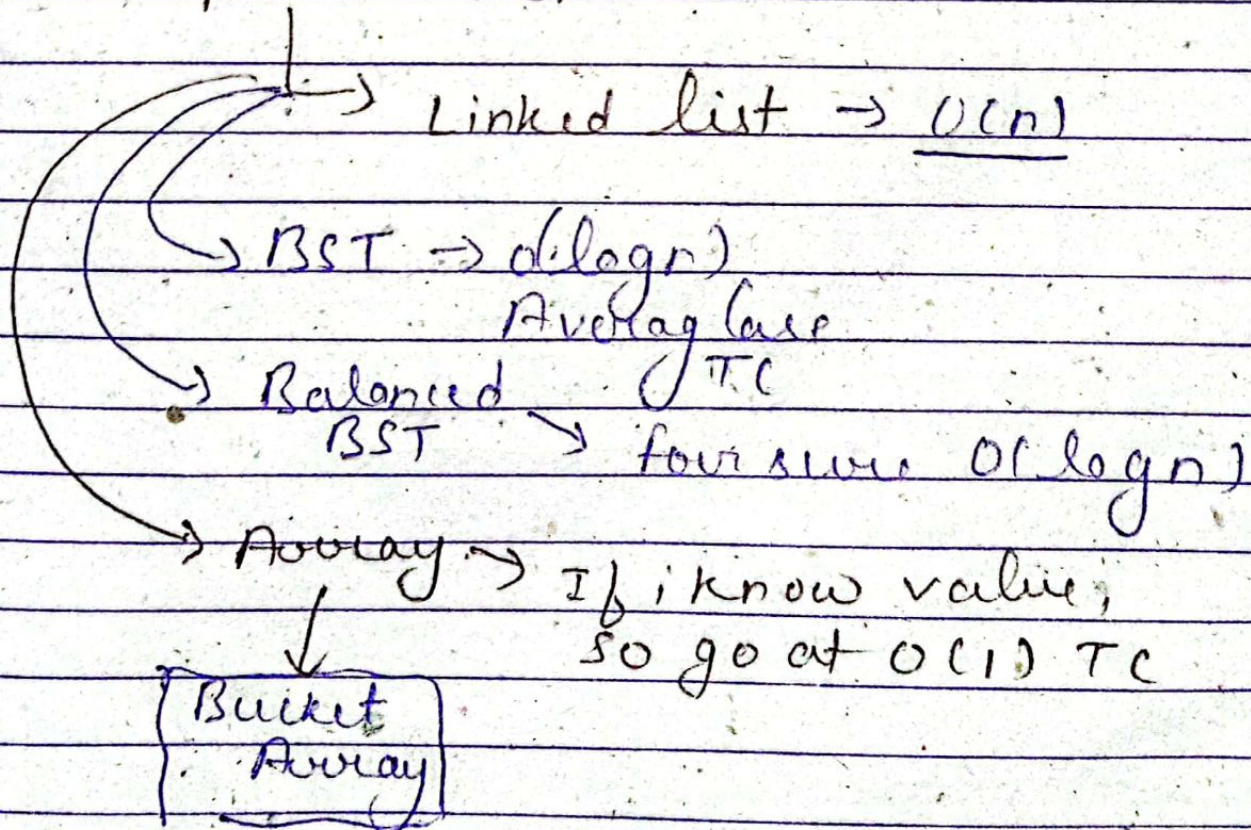

cout << mpp[" "] << endl

↓  
If element not exist in  
hashmap, ~~the~~ But we try to  
print corresponding value,

So it creat entry into map.  
Add 0 courses ponding its key.

Unordered Map → Implement via  
BST

Implement aion

love hello Ak → How we can map this string to index

'a' 'b' 'c' 'd'

$\text{char}[\text{ch} - \text{'a'}]++$

There is a term called Hash function

string

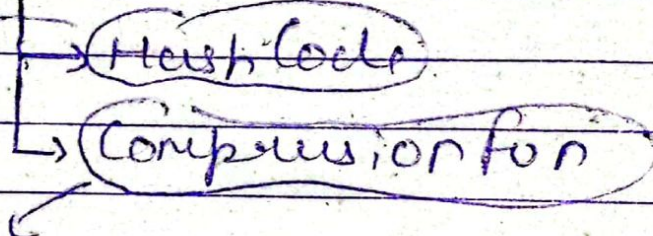

'love'

return Index  
oth index

Hash function

For conversion into numeric value

This for making Range

let's say love → 56

$$56 \% 26 = [0 \leftrightarrow 25] \text{ range.}$$

Hash  
Function

babbar

$$\begin{aligned}
 &h+a+b+b \\
 &+a+u \\
 &2+1+2+2 \\
 &+1+18
 \end{aligned}$$

26

compression  
fun
$$26 \div 26$$
0th  
index

babbar

Array

0th index

babbar → 26 →  $26 \div 26 = 0^{\text{th}}$  index

baaabbb → 26 →  $26 \div 26 = 0^{\text{th}}$  index

This is Collision

Make a hash function which has  
less no. of collision

# Collision Handling -

collision  
occurs

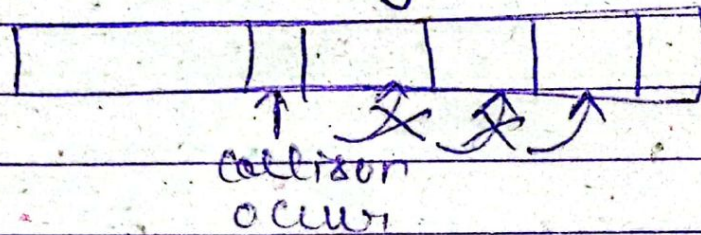

1) open Hashing

store data  
in all forms

2) Closed Hashing  $\rightarrow$  find next free space.

$\rightarrow$  Linear Probing  $f(i) \rightarrow i$

$\rightarrow$  Quadratic Probing  $f(i) = i^2$

How make a good Hash function

no. of element  $\Rightarrow n$   
free boxes  $\rightarrow b$

Load factor

Good Hash function
